Abstract

Over the past three decades, extensive field studies of wetland plant communities have been conducted in the Mississippi Alluvial Valley. These field studies have been carried out for various purposes under the auspices of federal and state research programs or in conjunction with Corps of Engineers project planning efforts. In the process, a wetland site classification approach has evolved based on hydrology, soils, and geomorphic setting. The research data and classification system have been recently used for a new purpose: to create a set of Potential Natural Vegetation (PNV) maps covering more than 26,000 square miles within the region. The purpose of PNV maps is to serve as blueprints for restoration planning and prioritization. Due to the fact that the hydrology of the landscape has been permanently changed by major flood control projects, the PNV maps do not represent the distribution of the original, pre-settlement vegetation. Rather, they identify the natural communities that are appropriate to the modern altered site conditions. By using these maps, persons interested in restoring particular tracts of land can identify the plant communities appropriate to the conditions present. Conversely, individuals interested in restoring particular plant communities can identify parts of the landscape that can support each respective type. The PNV maps are available for use in a Geographic Information System, where a range of complex restoration scenarios (such as the development of wildlife travel corridors or refuge areas) can be explored efficiently and alternative approaches can be compared to one another in terms of relative costs and ecological effectiveness. This report is one of six Field Atlases that present the same data in a downloadable, printable format at a scale of 1 inch = 1 mile.

Preface

The Mississippi Alluvial Valley (MAV) once contained the most extensive and diverse lowland forest in North America. The complexity and productivity of the ecosystem were the result of the dynamic behavior of the large rivers that have repeatedly migrated across the landscape, eroding and depositing sediments and periodically flooding millions of acres. Since the arrival of the first European settlers in the 19th century, the rivers have been stabilized and prevented from inundating most of the former floodplain, and agriculture has largely replaced the native vegetation. The deforestation of the MAV has been recognized for more than half a century as contributing to a variety of problems such as the extinction of wildlife species and pollution of receiving waters, including the Gulf of Mexico. Various government policies and private initiatives have been implemented to reverse this damage through restoration of native plant communities.

Ecologists working to restore natural systems in the MAV have sought to understand the fundamental changes that have occurred — particularly with regard to hydrology — and evaluate the effects of these changes on ecosystem function and restorability. The state of Arkansas, with funding from the Environmental Protection Agency (EPA), initiated much of the research in this area as part of a program to develop guidebooks for hydrogeomorphic (HGM) classification and assessment of wetlands. Various Corps of Engineers offices also participated in HGM-related studies as part of impact and alternatives analyses conducted for proposed federal flood control and water development projects in the MAV. The field data and spatial information developed for some of the projects in Arkansas provided the basis for the initial Potential Natural Vegetation (PNV) maps that were intended to be used to guide restoration planning over large areas. Since then, PNV maps have been developed for all of the MAV in eastern Arkansas, northwestern Mississippi, and northeastern Louisiana, with funding from diverse sources, including Corps of Engineers District offices, EPA, the state of Arkansas, and the U.S. Fish and Wildlife Service.

PNV maps were originally intended to be used in a geographic information system (GIS), where numerous possible options for restoration design can be explored and evaluated. However, as part of their PNV efforts, the Fish
and Wildlife Service also produced the first two Field Atlases—for Louisiana and Mississippi—and made the PNV maps available as downloadable products intended to be printed and bound for field use (http://www.lmvjv.org/bookshelf.htm). This format proved popular, so a set of four additional atlases covering the Arkansas portion of the MAV has been developed, the current atlas being one of them. All four of these documents are available for download at: (http://el.erdc.usace.army.mil/emrrp/analyt.html).

Charles Klimas, U.S. Army Engineer Research and Development Center (ERDC), Thomas Foti (Arkansas Natural Heritage Commission and Oakleaf Institute, Little Rock AR) and Jody Pagan (5-Oaks Wildlife Services, LLC, Stuttgart AR) developed the PNV concept and approach and have been the core mapping team across all of the basins. The original PNV maps upon which this atlas is based were developed for the Vicksburg District, Corps of Engineers, as part of the Southeast Arkansas Project, with the assistance of the State of Arkansas’ Multiagency Wetland Planning Team. R. Daniel Smith (ERDC) participated in the field effort and assembled and processed the original project GIS data. Malcolm Williamson (Center for Advanced Spatial Technologies, University of Arkansas, Fayetteville) updated and normalized that GIS data and prepared the maps that are included in this atlas.

While various sponsors participated in the development of the original maps, as described above, this series of Arkansas PNV Atlases was prepared and published under the Ecosystem Management and Restoration Research Program (EMRRP), within the Environmental Laboratory, ERDC, Vicksburg Mississippi. Glenn Rhett is EMRRP Program Manager. Dr. Al Cofrancesco is the ERDC Technical Director for the EMRRP.

COL Kevin J. Wilson is the Commander of ERDC, and Dr. Jeffery P. Holland is the Director.
1 Introduction

Studies of wetland plant communities in the Mississippi Alluvial Valley (MAV) over the past decade have produced a site classification approach based on hydrology and geomorphic setting. The approach is consistent with the “hydrogeomorphic” or HGM wetland classification system, but it has been adapted and refined specifically to support the development of detailed maps of the Potential Natural Vegetation (PNV) of the region. The purpose of PNV maps is to serve as a template for restoration planning and prioritization in a landscape that has been highly modified. Most of the bottomland hardwood forests and other native plant communities of the MAV were converted to agriculture during the 20th century. The remnants are largely those forest types that are adapted to the wettest sites where row cropping was infeasible. At the same time, tremendous local and federal effort has been expended on drainage, flood control, and navigation projects that have permanently altered the hydrology of the floodplain and alluvial terraces in the region. Consequently, the PNV maps are not designed to represent the distribution of the original, pre-settlement vegetation; rather, they identify the natural communities that are appropriate to the altered site conditions, hence the “potential” designation. This means that persons interested in restoring particular tracts of land can identify the plant communities appropriate to the various site conditions present. Conversely, individuals interested in restoring particular plant communities can identify parts of the landscape that could support each respective type. This information is available in GIS format, so various restoration scenarios can be explored and compared in terms of relative costs and ecological effectiveness.

This atlas covers the Boeuf-Tensas Basin, in southeast Arkansas. It has been created as a field reference for professionals who plan and conduct restoration projects in that area. The maps in this atlas (Appendix A) are produced at a scale of approximately 1:63,360 (1 inch = 1 mile). As an aid to orientation in the field, each PNV map is accompanied by the corresponding aerial image on the facing page, and both pages display major roads and towns. The pages immediately preceding the maps include master indexes to the map pages, using two different basemaps to provide an overview of the mapped PNV types as well as roads and towns for orientation. Also included in front of the map section is a map key that lists all of the PNV vegetation
community types present in the basin as well as the community classification code, typical site conditions, and common dominant species for each type. Appendix B follows with details on the characteristics of each community type; these details provide guidance regarding natural topographic features and plant species appropriate for restoration. The PNV approach, mapping criteria, and typical applications are described in more detail in a separate publication (Klimas et al. 2009).
2 The Boeuf-Tensas Basin

The mapped area is located in southeastern Arkansas (Figure 1), where it is bounded on the north and east by the mainstem levee systems along the Arkansas and Mississippi Rivers, and on the west by uplands. The basin continues into Louisiana to the south, but the coverage of this atlas extends only to the state line, incorporating approximately 1.24 million acres. A separate atlas covers the Louisiana portion of the basin as well as the adjacent Macon Ridge upland and Ouachita River lowland (Klimas et al. 2011a).

Figure 1. Location of the Boeuf-Tensas Basin in Arkansas.
There are two separate lowland areas partly separated by the northern end of Macon Ridge that are collectively referred to as the Boeuf-Tensas Basin. The Boeuf Basin is a narrow lowland on the west of Macon Ridge that consists of sediments deposited in past meander belts of the Arkansas River. It is named after the Boeuf River, but in Arkansas that stream flows entirely within the Macon Ridge uplands to the east before entering the lowlands in Louisiana. In Arkansas, the principal stream is Bayou Bartholomew, which flows within an abandoned course of the Arkansas River. To the east of Macon Ridge is the Tensas Basin, which is a very narrow area extending from the mouth of the Arkansas River into Louisiana, where it widens considerably. In Arkansas it consists primarily of backswamp deposits of the Mississippi River. Macon Ridge itself is a remnant of the glacial outwash that was deeply deposited throughout the MAV during periods of waning continental glaciation. For the purposes of this Atlas, the Boeuf-Tensas Basin is considered to include both of the two major lowland areas as well as the intervening portion of Macon Ridge and some parts of the adjacent modern meander belt of the Mississippi River where those areas lie west of the mainstem levee system.

Surface water entering the Boeuf-Tensas Basin arrives as precipitation or as runoff from the hills along the western flank of the basin. All drainage is to the south, leaving the Arkansas portion of the basin via Bayou Bartholomew, Bayou Macon, or the Boeuf River. Prior to construction of modern levees, major Mississippi and Arkansas River floods would have inundated most or all of the area, and poor internal drainage produced wet conditions over large areas even without flooding. Much of the natural drainage system has been deepened and straightened and ditches have been added to further improve drainage.
3 Using the PNV map as a model for restoration

The PNV mapping process was conceived as a way to provide the best available representation of restoration potential for the native plant communities of the MAV. One key aspect of these maps is that they reflect current, rather than historic, hydrologic patterns. This fundamental feature of the classification system — basing community designations on site conditions rather than species composition — also prevents misclassification of sites based on past management practices or other historic influences. The map legend (Appendix A) includes several ways of classifying the community types: by HGM subclass, for use with the corresponding HGM functional assessment guidebook (Klimas et al. 2011b); by site characteristics, which can be used to help guide site preparation; and by species dominance type, which lists species that frequently dominate on similar sites throughout the MAV. Note that these dominant species are not the only ones that should be included in a restoration plan for a site, and that sometimes one or more of the listed species are not common on a site type within a specific basin. Restoration planning should be based on the detailed and basin-specific community type descriptions in Appendix B. These descriptions reflect the probable long-term dominance patterns under current conditions. Forested sites sometimes will include species other than those that presently dominate. As a consequence of these characteristics, there are many possible uses for the PNV maps, including the following:

Replacement of critical habitat

The PNV mapping effort in Louisiana was initiated specifically to support restoration of potential habitat for the Ivory-Billed Woodpecker, which was prompted by its recent reported rediscovery in Arkansas. Foti et al. (2011) present a discussion of how PNV mapping can be used to help guide a restoration program of that type in the modern MAV landscape. Where critical habitat for other species is dependent on the composition, structure, and distribution of plant communities, the PNV maps can be used in similar ways to target the most effective sites for habitat restoration and population management.
Site-specific restoration design

Because the PNV maps often recognize mapping units of a fraction of an acre, they can normally inform restoration design even on relatively small or diverse sites. The site characteristics and geomorphic settings described in Appendix B indicate the extent to which a particular community tends to be affiliated with the ridges or swales of point bars; the almost-imperceptible vernal pools in backswamps; and similar subtle variations in topography that may have been moderated or eliminated by agricultural practices. Users should evaluate a particular site in light of these descriptions, and restore the appropriate topography prior to planting the area. If filling a ditch or breaking a levee is part of the restoration plan, the expected change in flood frequency will indicate establishment of a different plant community than the mapped unit, and that new “target” condition can be identified by consulting Appendix B. While all of these features will help guide restoration design, users are encouraged to adjust their site preparation and planting plans as needed based on their local knowledge, experience, and observations of actual conditions in the field. In particular, it is important to recognize that the accuracy of the community boundaries on the PNV map are limited by the precision and resolution of the underlying geomorphic, soils, and hydrology mapping, and that transitions between vegetation communities are normally more gradual than the distinct polygons on such maps imply. Similarly, where the modern hydrology is affected by structures such as roads and aquaculture impoundments, community boundaries may appear as straight lines. The authors have attempted to estimate the approximate true boundary if the structure is one that can be easily removed as part of a restoration project (e.g., a low catfish pond levee) but did not modify linear boundaries where the structure is unlikely to be removed (roads and flood-control levees) or where the topography, geomorphology, and soil data did not indicate a probable community transition location. In such cases the mapped feature appears as a rectangle and users should evaluate such modified sites individually prior to developing restoration specifications.

Landscape-level restoration planning

PNV maps can be useful for identifying restoration needs and opportunities where resource objectives involve the distribution of particular habitats over large regions. For example, in a GIS environment, it is relatively simple to identify sites appropriate for the restoration of extremely rare communities (e.g., prairies); sites that would support the maximum habitat diversity
within a single large block of restored forest; or the forest communities appropriate for restoration within various sections of a lengthy riparian corridor. PNV maps directly reflect flood frequency; therefore, restoration projects can be designed to assure that flood refuge areas are included in projects intended to provide habitat for terrestrial wildlife. Because the PNV maps use the HGM classification system, they reflect other wetland characteristics of potential interest. For example, the PNV map distinguishes between sites suitable for establishing Connected Depressions and Unconnected Depressions. Though these sites support the same forest communities, the latter is far more suitable for restoring amphibian populations due to the lack of predatory fish. There are numerous similar types of applications that can add flexibility and insight to the restoration planning process.

**Mitigation design**

The PNV maps have several obvious regulatory and planning applications. They can be used to find suitable locations for in-kind mitigation of project impacts, or to plan mitigation in a watershed context, as is currently encouraged in various federal programs. However, because the PNV maps use the HGM classification system, they can also be used in conjunction with HGM Regional Guidebooks to help calculate the appropriate amount of compensatory mitigation for particular wetland subclasses under various impact scenarios. The HGM guidebook for the Arkansas Delta Region (Klimas et al. 2011b) includes assessment models and recovery trajectories that can be used to estimate the degree to which restored wetlands perform certain functions over time. This means that restoration priorities can be adjusted to offset the loss of particular functions, or to favor restoration scenarios that will most quickly meet particular functional needs.

This atlas and other files and documents related to Potential Natural Vegetation mapping in the Mississippi Alluvial Valley can be downloaded from [http://el.erdc.usace.army.mil/emrrp/analyt.html](http://el.erdc.usace.army.mil/emrrp/analyt.html)

Appendix B: Potential Natural Vegetation Community Characteristics in the Boeuf-Tensas Basin, Arkansas

This Appendix describes the potential natural vegetation of the Boeuf-Tensas Basin of southeastern Arkansas. Since the purpose of the Field Atlas is to support ecosystem restoration design and planning, the focus is on the predominant long-term equilibrium community composition best adapted to persist on each site under the current hydrologic and climatic regime. This Appendix is also intended to call attention to the presence and scale of topographic features, such as natural levee ridges and shallow vernal pools, that are essential elements of most of the community types. Where those features have been significantly altered, they must be restored to their approximate original extent — prior to revegetation work — in order to establish the community types described here and mapped in the Field Atlas.

The dominant and associated species listed are primarily trees, since most restoration projects in the region focus on reforestation, but understory species or other characteristics strongly associated with a particular community type are noted in some cases. The listed species do not necessarily all occur together in any particular stand, but may all be found on similar sites where mature, compositionally stable communities are present. No early successional communities are described, although seral patches exist in all of the community types, and in some settings — such as point bars within and along active channels — they may be extensive. Similarly, the community descriptions do not necessarily reflect the current vegetation found on many sites, which may have established under a previous hydrologic regime or been extensively manipulated.

The community type names reflect the Hydrogeomorphic (HGM) Classification and landscape setting. See the map legend for the corresponding dominance-type designations.

### RB7  
**Frequently flooded lowlands**

- **Dominants:**  
  - Overcup oak  
  - Bitter pecan

- **Understory:**  
  - Swamp privet  
  - Palmetto

- **Associates on wetter sites:**  
  - Baldcypress  
  - Water tupelo

- **Associates on drier sites:**  
  - Nuttall oak  
  - Green ash  
  - Willow oak  
  - American elm  
  - Persimmon

**Description:**
This community type occurs on a wide variety of geomorphic settings and soil types where forest composition is strongly controlled by extended periods of backwater flooding in most years. The characteristic community is dominated by overcup oak, bitter pecan, and a limited group of associated canopy and understory species. Vines and ground cover species are less abundant and diverse than on less flooded sites. Dominance may shift to baldcypress and water tupelo in sumps and along minor interior drainageways. A more diverse species composition may develop on the margins of this type or on somewhat higher microsites within it.

Diverse communities of natural levees and upper banks of abandoned stream courses and active channels, as well as small tributary floodplains. Vegetation composition and structure on these sites is related to proximity to the channel and associated high flows, light availability, and sedimentation. Most of these sites are on substantial natural levee deposits, but active point bars occupied by pioneer riverfront species are included. They are also where large swales occur between levee deposits, narrow vernal pools support overcup oak, bitter pecan, and similar species.

### F1
**High natural levees**

</tr>
</tbody>
</table>

High, well-drained linear features that were originally formed along the banks of the Arkansas or Mississippi Rivers, though they may be far removed from those rivers now. They are diverse sites of marginal wetland character, and may have substantial slope, but are classified as flats because the principal source of water is precipitation. Giant cane is usually present in the understory. Cottonwood is common only within the most recent Mississippi River meander belt. Sycamore is common only on the Arkansas River deposits.
| Dominants: | White oak  
|           | Willow oak |
|           | Cherrybark oak  
|           | Water oak  
|           | Sweetgum  
| Associates: | Cow oak  
|           | Sugarberry  
|           | Shagbark hickory  
| F2 | Well-drained recent alluvium in lowlands  
| Dominant species: | Water oak  
|           | Sweetgum  
| Associates: | Delta post oak  
|           | Cedar elm  
|           | Blackgum  
|           | Pecan  
|           | Sugarberry  
| Vernal pools: | Overcup oak  
|           | Nuttall oak  
| Relatively flat topographic settings of older backswamps, point bars, and tributary terraces. Cherrybark oak is characteristic and palmetto is usually present. Vernal pools are common but not large. Extensive tracts of this type have been cleared and leveled for agriculture, and restoration requires re-establishment of vernal pools to store precipitation and maintain the original wetland character and diversity. |
| F3 | Well-drained older alluvium in lowlands  
| Dominants: | Nuttall oak  
|           | Sweetgum  
|           | Willow oak  
| Associated species: | Cedar elm  
|           | Water oak  
|           | Green ash  
|           | Persimmon  
|           | American elm  
|           | Sugarberry  
| Vernal pools: | Overcup oak  
|           | Baldcypress  
| Poorly drained, often ponded ridge-and-swale topography or flats, usually strongly dominated by Nuttall oak or willow oak, and with cedar elm consistently present. Vernal pools tend to be long, arcuate features in point bar swales, and some include baldcypress at the deepest points. |
| F5 | Poorly drained Mississippi River sediments  
| Dominants: | Nuttall oak  
|           | Sweetgum  
|           | Willow oak  
| Vernal pools: | Overcup oak  
| Baldcypress  
| Poorly drained flats, primarily in backswamp deposits of Arkansas River origin, dominated by Nuttall oak. Palmetto is characteristic in the understory. Large shallow vernal pools are common. Better-drained sites within this type |
| F6 | Poorly drained lowlands  
| Dominants: | Nuttall oak  
|           | Cherrybark oak  
| Associates: | Green ash  

Diverse communities on well-drained sites not subject to regular flooding. Commonly on natural levee and point bar deposits, including those along abandoned channel segments such as oxbow lakes. Also found on some older surfaces, such as tributary terraces. Water oak and cherry bark oak are characteristic.
Vernal pools: Cedar elm

Often include cherrybark oak. Wet conditions and extensive ponding have deterred clearing in many places.

<tbody>
<tr>
<td><strong>D1</strong>&lt;br&gt;Stream-connected and unconnected depressions in abandoned channels</td>
<td>Dominants:&lt;br&gt; - Baldcypress&lt;br&gt; - Water tupelo&lt;br&gt; - Overcup Oak&lt;br&gt; - Bitter pecan&lt;br&gt;&lt;br&gt;Understory and associated species:&lt;br&gt; - Water elm&lt;br&gt; - Waterlocust&lt;br&gt; - Swamp privet&lt;br&gt; - Buttonbush&lt;br&gt; - Swamp cottonwood</td>
<td>Topographic depressions with very poorly drained soils in former stream channels and large swales. Connected depressions are connected to downstream systems by a perennial stream channel or are within the 5-year floodplain. Unconnected depressions meet neither of these criteria. Species composition is restricted to the most water-tolerant plants, a factor that helps individuals distinguish true depressions from vernal pools. Vines and ground cover species are uncommon.</td>
</tr>
<tr>
<td><strong>D2</strong>&lt;br&gt;Stream-connected depressions on Pleistocene outwash terraces</td>
<td>Dominants:&lt;br&gt; - Overcup oak&lt;br&gt; - Baldcypress&lt;br&gt; - Water tupelo&lt;br&gt; - Water elm&lt;br&gt;&lt;br&gt;Associates:&lt;br&gt; - Bitter pecan&lt;br&gt; - Drummond’s red maple&lt;br&gt; - Green ash&lt;br&gt; - Persimmon&lt;br&gt;&lt;br&gt;Included Interfluvies:&lt;br&gt; - Nuttall oak&lt;br&gt; - Willow oak&lt;br&gt; - Delta post oak&lt;br&gt; - Cherrybark oak&lt;br&gt; - Sweetgum&lt;br&gt; - Sugarberry</td>
<td>These Valley Train Ponds are depressions that occur in the remnants of glacial outwash channels on Pleistocene valley train terraces. The original coarse channel materials have mostly been veneered with fine-grained sediments and support swamp and floodplain species. Localized areas where the veneer is thin may be sandy and support individual trees or small groups of riverfront species such as river birch and sycamore. Small areas of higher ground (interfluvies) not identified on soils maps are included in these units.</td>

<tbody>
<tr>
<td><strong>FR1</strong>&lt;br&gt;Stream-connected and unconnected lake and pond fringe wetlands</td>
<td>Common dominants in systems with natural fluctuation patterns:&lt;br&gt; - Baldcypress&lt;br&gt; - Water tupelo&lt;br&gt; - Buttonbush</td>
<td>Wetlands within permanent lakes and ponds, including borrow pits, but not aquaculture ponds. Natural systems typically support baldcypress and tupelo forests within the fluctuation zone and in the immediate lakefront zone where water tables remain near the surface. Buttonbush thickets may dominate in shallow, near-permanent water, and</td>
</tr>
</tbody>
</table>
Numerous herbaceous species

Common dominants in systems with highly modified fluctuation patterns:
- Black willow
- Buttonbush
- American lotus

zones of emergent species are usually present, with erect rooted species in shallow water, floating-leaved species in deeper water, and submerged aquatics present throughout the open water area. Where water levels are manipulated, these patterns are usually altered in various ways. Because water depths and fluctuation patterns are unknown, the entire water body is mapped as fringe wetland. Connected fringe wetlands are connected to downstream aquatic systems by a perennial stream channel or are within the 5-year floodplain. Unconnected fringe wetlands meet neither of these criteria.

| U2 | Dominant species:  
Southern red oak  
Cherrybark oak  
Water oak  
Sweetgum  
Shagbark hickory  
Associated species:  
Post oak  
Willow oak | Upland forests of the Pleistocene terraces and alluvial fans. Species composition can vary widely depending on local soils and drainage conditions, but generally is similar to other upland forests of the West Gulf Coastal Plain region. |
| U3 | Dominants:  
Southern red oak  
Post oak  
Water oak  
White oak  
Associated species:  
Cherrybark oak  
Cow oak  
Vernal pools:  
Swamp cottonwood  
Overcup oak  
American elm  
Persimmon  
Willow oak  
Green ash | Upland forests that include a range of community types which reflect differing soil and drainage conditions. Vernal pools may occur in the remnant ancient channels of the Arkansas River, as well as changes in fire. |
Over the past three decades, extensive field studies of wetland plant communities have been conducted in the Mississippi Alluvial Valley. These field studies have been carried out for various purposes under the auspices of federal and state research programs or in conjunction with Corps of Engineers project planning efforts. In the process, a wetland site classification approach has evolved based on hydrology, soils, and geomorphic setting. The research data and classification system have been recently used for a new purpose: to create a set of Potential Natural Vegetation (PNV) maps covering more than 26,000 square miles within the region. The purpose of PNV maps is to serve as blueprints for restoration planning and prioritization. Due to the fact that the hydrology of the landscape has been permanently changed by major flood control projects, the PNV maps do not represent the distribution of the original, pre-settlement vegetation. Rather, they identify the natural communities that are appropriate to the modern altered site conditions. By using these maps, persons interested in restoring particular tracts of land can identify the plant communities appropriate to the conditions present. Conversely, individuals interested in restoring particular plant communities can identify parts of the landscape that can support each respective type. The PNV maps are available for use in a Geographic Information System, where a range of complex restoration scenarios (such as the development of wildlife travel corridors or refuge areas) can be explored efficiently and alternative approaches can be compared to one another in terms of relative costs and ecological effectiveness. This report is one of six Field Atlases that present the same data in a downloadable, printable format at a scale of 1 inch = 1 mile.
